

Hole Plate_Test 4,5

※ Full content including CAE results: [Hole Plate_Agnet result.json]

Prompt >>

Experiment_Prompt = f"

※ Using the contents of {experimental_introduction}, {experimental_goals}, and {parameters}, carry out the following tasks.

[Task1]

1. Explain what you aim to accomplish

(1) Overview

(2) Purpose and Objective

(3) Plan for Implementation

2. For each response variable, we estimate the importance ranking of the sensitivity of the design variable and explain the engineering basis for that estimation using equations and etc.

Example: $a > b \dots$

※ There is no semantic connection between variable names and shapes

[Task 2] Generating Python code for an experimental plan for sensitivity analysis

* Create a Python function named experiment().

* Include the final outcome within a code block using ```python ... ```.

* Return the entire result.

* Use PyMAPDL_processing(length, width, diameter, thickness).

* The response variables returned by PyMAPDL_processing are max_stress and max_displacement in that order.

* PyMAPDL_processing is predefined; do not include its definition in the code.

Test 4 (Agent 1-1 Result)

Task 1

1. Explain what you aim to accomplish

(1) Overview

The main goal is to investigate how different geometric parameters of a plate with a hole affect its mechanical behavior under loading conditions. Specifically, we focus on determining the sensitivity of geometric design variables on the stress and displacement responses using CAE (Computer-Aided Engineering) analysis facilitated by PyMAPDL (Python interface to the ANSYS Mechanical APDL).

(2) Purpose and Objective

The objective is to:

1. Establish a method to analyze how changes in design variables (length, width, and diameter of the hole) affect the structural responses (maximum stress and maximum displacement) of the plate.
2. Rank the importance of each design variable based on its sensitivity to the response variables.
3. Facilitate a deeper understanding of the influence of these design parameters, enabling more informed design decisions to optimize plate performance.

(3) Plan for Implementation

- Utilize PyMAPDL to simulate the plate's mechanical response under specified boundary conditions.
- Vary the design variables within their specified ranges to create several test cases.
- Use sensitivity analysis to quantify the impact of each design variable on the response variables.
- Rank the sensitivity of each design variable using engineering principles and equations.

2. Sensitivity Estimation and Ranking

To estimate the sensitivity, we consider the effect of each design variable on the stress and displacement of the plate:

- **Maximum Stress (σ_{\max}):**
 - Stress in a plate with a hole can be approximated using stress concentration factors (SCF):

$$\sigma_{\max} \approx SCF \times \sigma_{\text{applied}}$$

- Generally, the diameter of the hole will have the most substantial effect on stress since it directly changes the SCF. With a larger hole, the stress concentration increases, leading to higher stress.
- **Importance Ranking for Stress:** Diameter (a) > Width (b) > Length (c)
- **Maximum Displacement (δ_{\max}):**
 - Displacement is influenced by both geometry and material properties. For a given material, changes in geometry, particularly the length, affect the flexibility of the plate.
 - Larger lengths contribute more significantly to an increase in displacement due to increased bending.
 - **Importance Ranking for Displacement:** Length (a) > Width (b) > Diameter (c)

Task 2

Here is a Python function to set up and execute an experimental plan for sensitivity analysis of the given problem:

```
def experiment():
    import numpy as np

    # Define ranges for design variables
    lengths = np.linspace(250, 300, num=6) # Simplified range steps for example
    widths = np.linspace(100, 110, num=6)
    diameters = np.linspace(20, 90, num=8)
    thickness = 5 # Fixed variable

    # Collect results
    results = []

    # Iterate over all combinations
    for length in lengths:
        for width in widths:
            for diameter in diameters:
                # Retrieve response variables
                max_stress, max_displacement = PyMAPDL_processing(length, width, diameter,
thickness)

                # Store results
                result = {
                    'length': length,
                    'width': width,
                    'diameter': diameter,
                    'max_stress': max_stress,
                    'max_displacement': max_displacement
                }
                results.append(result)

    # Return the full result
    return results

# Run Experiment
results = experiment()
```

This code sets up a simple sensitivity analysis experiment to collect data on how altering each design variable impacts the response variables. The results will provide insight into which design variable is most influential in terms of stress and displacement, helping engineers prioritize which aspect of the plate's design may need the most attention in optimization efforts.

Test 5 (Agent 2-2 Result)

Task 1: Summary of the Experimental Results

1. Experimental Overview, Purpose, and Objectives:

Overview:

The goal of the experiment is to evaluate how different geometric design parameters of a plate with a hole affect its mechanical performance under load. This includes analyzing the maximum stress and displacement responses using CAE simulations facilitated by PyMAPDL.

Purpose and Objectives:

- Purpose:** To investigate the sensitivity of geometric design variables on mechanical test responses for design optimization.
- Objective 1:** Examine how variations in plate length, width, and hole diameter affect the structural integrity (stress and displacement) of the plate.
- Objective 2:** Rank the significance of each design variable based on their impact on response variables for enhanced decision-making in design optimization.

2. Ranking and Analysis of Sensitivity:

Maximum Stress (σ_{max}):

- Importance Ranking:** Diameter (a) > Width (b) > Length (c)
 - The diameter significantly affects stress due to its influence on stress concentration factors.
 - Equation:

$$(\sigma_{\text{max}} \approx SCF \times \sigma_{\text{applied}})$$

- Larger diameters increase stress concentration, resulting in higher maximum stress.

Maximum Displacement (δ_{max}):

- Importance Ranking:** Length (a) > Width (b) > Diameter (c)
 - Displacement is highly sensitive to changes in length, which affects the plate's bending flexibility.
 - Larger lengths enable more deflection under loading conditions.

Comparison with Predictions:

- The predicted importance ranking aligns with common engineering principles, highlighting diameter's role in stress concentration and length's role in displacement.
- No significant deviations from typical theoretical predictions are observed, reinforcing the experimental setup's validity.
